Syntax

APPLYING FUNCTIONS ELEMENT-WISE

• Apply a function element-wise to a series:

```
df[col_name].apply(function_name)

df[col_name].map(function_name)
```

• Apply a function element-wise to a dataframe:

```
df.applymap(function_name)
```

APPLYING FUNCTIONS ALONG AN AXIS

• Apply a function along an axis, column-wise:

```
df.apply(function_name)
```

RESHAPING DATAFRAMES

• Reshape a dataframe:

```
pd.melt(df, id_vars=[col1, col2], value_vars=[col3, col4])
```

Concepts

• The **Series.apply()** and **Series.map()** methods can be used to apply a function element—wise to a *series*. The **DataFrame.applymap()** method can be used to apply a function element—wise to a *dataframe*.

- The DataFrame.apply() method has different capabilities than the Series.apply() method.

 Instead of applying functions element—wise, the df.apply() method applies functions along an axis, either column—wise or row—wise. When we create a function to use with df.apply() , we set it up to accept a Series, most commonly a column.
- Use the <a href="https://example.com/apply.c
